ABSTRACT

The solar energy is the language of this age. It is renewable, clean and almost without cost. This research is focusing on utilizing of renewable energy in air purification process. As known, our environment is full with industrial waste gases, such as SO_x, NO_x, CO_x, CH₄, H₂S etc. To reduce percentage concentration of these gases, solar energy is used to generate a convection stream within a metal black column. Polluted air consists of industrial waste gases, while passing through the column, it will contact with baffles of an activated carbon plates, fixed horizontally to increase the contact area with gases. The activated carbon is a common adsorbent with tremendous adsorption capability. So it will remove waste gases from polluted air. The three-dimensional steady-state continuity, Navier-Stokes, energy, radiation, natural convection, species transport for CO₂ physical adsorption and multiphase Eulerian-granular model equations are solved under turbulent condition, using the commercially available Computational Fluid Dynamics software Fluent. The quality of the solutions obtained from these simulations is largely within the acceptable range proving that Computational Fluid Dynamics is an effective tool for predicting the behavior and performance of a solar air filter.

Keywords: *Solar air filter, CO₂ species transport, Activated carbon.*

1. INTRODUCTION

The atmospheric concentration of CO₂ has increased dramatically over the last two centuries, and this increase has a significant impact on the environment, contributing to climate change and the acidification of the oceans. Researchers and scientists agree that a decrease in CO₂ emissions into the atmosphere is highly desired. Carbon dioxide capture and storage (CCS) is attracting attention lately as a measure for reducing CO₂ gas emissions substantially and rapidly [1]. The adsorption method is a promising alternative to chemical absorption due to its

advantages in terms of energy savings and ease of operation. Three key requirements must be met to develop CO₂ adsorbents: (a) ability to adsorb a large amount of CO₂ > 4.4wt % (b) extended working life, (c) low energy demands for regeneration [2]. Activated carbon has been most extensively used for CO₂ adsorption due to their high specific surface area and good physicochemical properties. Moreover, the performance of carbon materials as adsorbents depends on the combination of porous and chemical surface properties [3]. However, the higher adsorption capacity of CO₂ on activated

carbon was obtained at a lower temperature. The activated carbon used in this research is the activated charcoal. It is a form of carbon processed to have small, low volume pores that increase the surface area available for adsorption process, due to its high micro porosity, just one gram of this activated carbon has a surface area in excess of 500 m² [4]. There are number of researchers work on fixed bed solid adsorption process to separate solvent vapour. Takeuchi et al practically proved that the effect of solvent vapor was governed by surface diffusion for air having velocity above 0.2 m/s [5]. Eventually, Jean-Noel Baleo et al numerically and experimentally compared pressure drops in carbon cloths adsorption medium [6]. Two groups experimentally studied the CO₂ adsorption thermodynamics effect at different temperatures by using vacuum adsorption apparatus [7-8]. Pressure swing adsorption process with activated carbon bed to extract carbon dioxide and methane from pure gases was experimentally studied by Goetz et al at two different temperatures (273 and 298 K) and for pressure up to 1MPa [9]. Pevida et al performed an experiment to study surface modification effect of activated carbon on CO₂ capture through X-ray photoelectron spectroscopy [10]. Berger and Bhown developed a theoretical model for optimizing solid sorbent for CO₂ capture [11]. One of the researchers who performed experiments on activated carbon and zeolite 13X for CO₂, N₂ and CH₄ [12]. Hauchhum and Mahanta also followed same procedure with Zeolites 13X, zeolite 4A and activated carbon using temperature swing adsorption method [13]. The maximum CO₂ sorption capacity on the synthesized activated carbon is found to be 80 mg CO₂ per gram adsorbent. The research was indicated that the most of the researchers are working with experimental and theoretical

method for pressure swing and gravimetric adsorption method with fix bed by using activated carbon or its alternatives, as an adsorption material [14]. Very few researchers are applying numerical method to predict CO₂ adsorption on activated carbon bed. Nough et al performed numerical simulation on fixed bed adsorption column using integrated approach to predict the effect of various influencing parameters such as feed velocity, bed porosity and feed concentration [15]. They investigated their influences on the CO₂ adsorption capacity besides the effect of inlet CO₂ concentration on the bed temperature profile. Ryan et al applied multi-phase CFD modelling on solid sorbent carbon capture fluidized bed system with silica supported amine adsorbent material [16]. CFD simulation studies were carried out to determine the separation length required for complete separation of the feed mixture corresponding to different inlet feed concentrations which were entering the column at a given flow rate. Pierre recently, worked on computational investigation of CO₂ capture using activated carbon in a packed bed and optimization of various parameters to improve efficiency of the process [17]. However, none of the researchers applied radiation, natural convection, species transport, multiphase and turbulent flow condition on activated carbon fix bed to simulate CO₂ adsorption effect. So, these numerical parameters will be considered in this study. The commercially available CFD software Fluent 14.1 will be used for this simulation.

2. CFD MODEL SETUP AND ANALYSIS

2.1 GENERAL

The geometry was created in Ansys Design Modeler with bed size 40 x 30 x 0.1 cm³ fitted

inside rectangular column having dimension 40x 40 x 30 cm as shown in Figure 1.

Fig 1 Schematic of the column model with feed inlet and outlet.

The domain was then meshed as shown in Figure 2 and model was subsequently set up in Ansys Fluent 14.1[18].

Fig. 2. Ansys Meshing of column model

The details of the adsorption column model were taken from earlier related work [17-18]. The fluid was taken to be incompressible, Newtonian, and in a turbulent flow regime with mix radiation and natural convection effects. Normal atmospheric air with 0.20 % H₂O, 0.23 % O₂, 0.10% CO₂ and 47% N₂ mass fraction conditions was chosen as the feed mixture. The multi-phase Eulerian model with granular mass transfer approach was used in activated carbon domain. The simulation of the fluid flow in that fixed bed since the adsorbent inside the activated carbon packed bed can be treated as porous medium having porosity 0.42 mm. The mixing and transport of binary species are

modeled by solving conservation equations describing convection and diffusion for each component species. The following assumptions have been made in the modeling approach.

- Heat transfer within bed is negligible.
- The mass transfer is represented by linear driving force (LDF) model.
- The porosity in granular media domain is considered as uniform throughout.

2.2 GOVERNING EQUATION FOR ADSORPTION COLUMN

Eulerian granular multiphase model continuity equation for phase: The general 3-D continuity equation for unsteady fluid flow is;

$$\frac{\partial(\alpha_q \rho_q)}{\partial t} + \nabla \cdot (\alpha_q \rho_q \vec{v}_q) = \sum_{p=1}^n (\dot{m}_{pq} - \dot{m}_{qp}) + S_q \quad (1)$$

Where $\vec{v}_q$ is the velocity of phase q and $\dot{m}_{pq}$ characterizes the mass transfer from the pth to qth phase, and $\dot{m}_{qp}$ characterizes the mass transfer from phase q to phase p, and you are able to specify these mechanisms separately.

S_q is a source term.

2.3 CONSERVATION OF MOMENTUM

The momentum balance for phase q yields.

$$\begin{aligned} & \frac{\partial(\alpha_q \rho_q \vec{v}_q)}{\partial t} + \nabla \cdot (\alpha_q \rho_q \vec{v}_q \vec{v}_q) \\ &= -\alpha_q \nabla p + \nabla \cdot \bar{\bar{\tau}}_q + \alpha_q \rho_q \vec{g} \\ &+ \sum_{p=1}^n (\vec{R}_{pq} + \dot{m}_{pq} \vec{v}_{pq} - \dot{m}_{qp} \vec{v}_{qp}) \\ &+ (\vec{F}_Q + \vec{F}_{lift,Q} + \vec{F}_{vm,Q}) \end{aligned} \quad (2)$$

Where $\bar{\bar{\tau}}_q$ is the qth phase stress-strain tensor,

$$\bar{\bar{\tau}}_q = \alpha_q \mu_q (\nabla \vec{v}_q + \nabla \vec{v}_q^T) + \alpha_q \left(\lambda_q \frac{2}{3} \mu_q \right) \nabla \cdot \vec{v}_q \vec{I} \quad (3)$$

$\vec{v}_{pq}$ is the interphase velocity, defined as follows. If $\dot{m}_{pq} > 0$ (i.e., phase p mass is being

transferred to phase q), $\vec{v}_{pq} = \vec{v}_p$; if $\dot{m}_{pq} < 0$ (i.e., phase q mass is being transferred to phase p), $\vec{v}_{pq} = \vec{v}_q$. Likewise, if $\dot{m}_{qp} > 0$ then $\vec{v}_{qp} = \vec{v}_q$, if $\dot{m}_{qp} < 0$ then $\vec{v}_{qp} = \vec{v}_p$. Interphase force $\vec{R}_{pq}$. This force depends on the friction, pressure, cohesion, and other effects, and is subject to the conditions that $\vec{R}_{pq} = -\vec{R}_{qp}$ and $\vec{R}_{qq} = 0$

$$\sum_{p=1}^n (\vec{R}_{pq}) = \sum_{p=1}^n K_{pq} (\vec{v}_p - \vec{v}_q) \quad (4)$$

Where $K_{pq}(=K_{qp})$ is the interphase momentum exchange coefficient. For the multiphase flow the effect of lift forces were considered on the secondary phase particles. These lift forces act on a particle mainly due to velocity gradients in the primary-phase flow field. The lift force will be more significant for larger particles, but in this paper, model assumes that the particle diameter is much smaller than the inter-particle spacing. Thus, the inclusion of lift forces is not appropriate for closely packed particles or for very small particles. The lift force is insignificant compared to the drag force, so there is no reason to include this extra term. The drag coefficient is considering Syamlal-Obrien equation which is more appropriate for solid to gas phase interaction.

2.4 SPECIES TRANSPORT WITHOUT REACTION EQUATIONS

The local mass fraction of each species, Y_i , through the solution of a convection-diffusion equation for the i^{th} species can be predicted. This conservation equation takes the following general form:

$$\frac{\partial}{\partial t}(\rho Y_i) + \nabla \cdot (\rho \vec{v} Y_i) = -\nabla \cdot \vec{J}_i + R_i + S_i \quad (5)$$

We are considering flow become turbulent so mass diffusion in the following form:

$$\vec{J}_i = \left(\rho D_{i,m} + \frac{\mu_t}{Sc_t} \right) \nabla Y_i \quad (6)$$

No special solution procedures are usually required for a non-reacting species transport calculation.

2.5 DISCRETE ORDINATES (DO) RADIATION MODEL

The discrete ordinates (DO) radiation model solves the radiative transfer equation (RTE) for a finite number of discrete solid angles. The DO model considers the radiative transfer equation (RTE) in the direction $\vec{s}$ as a field equation.

$$\begin{aligned} & \nabla \cdot (I(\vec{Y}, \vec{s}) \vec{s}) + (a + \sigma_s) I(\vec{Y}, \vec{s}) \\ &= an^2 \frac{\sigma T^4}{\pi} + \frac{\sigma_s}{4\pi} \int_0^{4\pi} I(\vec{Y}, \vec{s}^t) \Phi(\vec{s} \cdot \vec{s}^t) d\Omega^t \end{aligned} \quad (7)$$

2.6 SIMULATION BOUNDARY CONDITION

The simulation domain operated at 1 bar pressure and 303 K temperature. Same boundary condition set at wall to define natural convection. The atmospheric air inlet velocity is set at 0.1 m/s with 0.20 % H₂O, 0.23 % O₂, 0.10% CO₂ and 47% N₂ mass fraction.

3. RESULTS AND DISCUSSION

The integrated CFD model was used to determine CO₂ mass fraction at the column outlet for different time based on set operating conditions. The results simulated using the CFD model. Based on the good agreement of the model results as shown in Figure 3, which was useful to study the effect of CO₂ concentration on the adsorption performance. It is clearly presented that CO₂ mass concentration is gradually decreasing with increasing height of the column.

Fig. 3. Mass fraction of CO₂

4. CONCLUSION

The CFD simulation is a useful tool to conceptual system design and testing. It is helpful to predict the CO₂ mass fraction with single activated carbon adsorbed plate. The result was presented an equitable mode for the effect of feed velocity, bed porosity and CO₂ inlet concentration on single stack of activated carbon. This study also showed that the effect of granular bed significantly influences the performance and capability of the adsorption process. Hence, it is completely justify our concept.

ACKNOWLEDGEMENTS

The simulation was performed at Yanbu Research Center, Computational Lab. Yanbu, Kingdom of Saudi Arabia.

الملخص:

ان الطاقة الشمسية هي لغة هذا العصر، وهي طاقة متجددة ونظيفة وبدون تكلفة تقريبا، لذلك يركز هذا البحث على استخدام الطاقة الشمسية في عملية تنقية الهواء. وكما هو معلوم، فإن بيئتنا مليئة بغازات النفايات الصناعية، مثل أكاسيد الكبريت وأكاسيد النيتروجين وأكاسيد الكربون والميثان وكبريتيد الهيدروجين الخ. ولتقليل نسبة تركيز هذه الغازات تستخدم الطاقة الشمسية لتوليد تيار حمل حراري داخل برج معدني أسود (لامتصاص أكبر قدر ممكن من الطاقة الشمسية). حيث يمر الهواء الملوث المتكون من غازات النفايات الصناعية من خلال البرج لتصطدم أثناء صعودها مع حواجز من لوحات الكربون المنشط المثبتة أفقياً على جانبيين متقابلين من البرج بحيث يتم امتزاز هذه الغازات على اسطح هذه الألواح والمكونة من حبيبات الكربون المنشط المضغوطة، حيث يتمتع الكربون المنشط بقدرة امتصاص هائلة. لذلك سوف يعمل على إزالة غازات النفايات من الهواء الملوث. ولضمان الحصول على نتائج دقيقة لتغيير قيم تركيز الغازات الضارة (ممثلة بغاز ثاني أكسيد الكربون في هذا البحث) مع تغيير الارتفاع داخل البرج، فقد تم حل معادلات النموذج: استمرارية الحالة ثلاثية الأبعاد، Navier-Stokes، الطاقة، الإشعاع، الحمل الحراري الطبيعي، نقل الأنواع للامتزاز الفيزيائي لثاني أكسيد الكربون، Eulerian-granular في ظل حالة مضطربة، وذلك باستخدام برنامج Computational Fluid Dynamics software Fluent. ان جودة الحلول التي تم الحصول عليها من هذه المحاكاة تقع إلى حد كبير ضمن نطاق مقبول مما يثبت أن ديناميكيات الموائع الحسابية أداة فعالة للتنبؤ بسلوك وأداء فلتر الهواء الشمسي.
